A Biologically-centered framework in Urban foodscapes

The phd research covers the distinct topics of food, architecture, senses and urbanism, explored through the distinct study of organoleptic qualities in urban foodscapes, as a way to explore food systems on both the macro and micro levels. Foodscapes refers to food-related places in cities where food is produced, consumed, traded, and distributed, Whereas Urban Organoleptic refers to spaces in cities that are capable of stimulating the senses. In the move to make food more accessible in the urban fabric, through a rising movement in urban agriculture, re-imagining the urbanscape as partially a farm and food 'scape' responds to societal challenges around food security and rising urbanisation, and could render these spaces as active and participatory social entities as well as places of ecological well-being and awareness towards sustainable urban development.
